## Learning Paradigms

Imagine an organism or machine that experiences some of sensory inputs:

$$
\mathbf{E}=x_{1}, x_{2}, x_{3}, x_{4}, \ldots
$$

- Supervised learning: given the desired outputs $y_{1}, y_{2}, \ldots$, learn to produce the correct output given new input
- Unsupervised learning: exploit regularities in E to build a representation that can be used for reasoning or prediction

We have another learning paradigm, but we won't go into its details

- Reinforcement learning: producing actions $a_{1}, a_{2}, \ldots$ which affect the environment, and receiving rewards $r_{1}, r_{2}, \ldots$ learn to act in a way that maximizes rewards in the long term

If you are curious check out http://www-anw.cs.umass.edu/ rich/book/the-book.html

## Neural Networks <br> - Introduction -

## Why should we care about Neural Networks?

Everyday computer systems are good at:

- Doing precisely what the programmer programs they to do
- Doing arithmetic very fast

But we whould like them to:

- Interact with noisy data or data from the environment
- Be massively parallel and fault tolerant
- Adapt to circumstances

We should look for a computational model other than Von Neumann Machine!

## The Biological Neuron

In the brain we have:

- $10^{11}$ neurons
- $10^{4}$ synapses per neurons

The computational model of the brain is:

- Distributed among simple units called neurons
- Intrinsically parallel
- Redundant and thus fault tolerant

## Computation in Biological Neurons

Information is transmitted through chemical mechanisms:

- Dendrites collect input charges from synapses
- Inhibitory synapses with different weight
- Excitatory synapses with different weight
- Axon transmit accumulated charges through synapses
- Once the charge is above a threshold the neuron fires

## The Artificial Neuron

In this simple model of neuron $j$ we can identify:

- The synaptic weights or simply weights $w_{j i}$
- The activation value $z_{j}=\sum_{i} w_{j i} s_{i}$
- The activation threshold or bias $b_{j} \doteq-w_{j 0} \cdot 1$
- The activation function $g_{j}($.

The final output of neuron $j$ is: $s_{j}=g_{j}\left(\sum_{i=1}^{N} w_{j i} s_{i}-b_{j}\right)=g_{j}\left(\sum_{i=0}^{N} w_{j i} s_{i}\right)$

## Common Activation Functions

Sign function: $g\left(z_{j}\right)= \begin{cases}1 & \text { if } z_{j}>0 \\ 0 & \text { if } z_{j}=0 \\ -1 & \text { if } z_{j}<0\end{cases}$

Linear function: $g\left(z_{j}\right)=z_{j}$

Sigmoid function: $g\left(z_{j}\right)=\frac{1}{1+e^{-z_{j}}}$

Hyperbolic tangent: $g\left(z_{j}\right)=\frac{e^{z_{j}}-e^{-z_{j}}}{e^{z_{j}}+e^{-z_{j}}}$

## The Perceptron

The first model of neuron proposed was the Perceptron:

What can I do with such a simple model?

## The Perceptron as a Logic Operator

Perceptron as a logic AND

Perceptron as a logic OR

## How does it work?

We can compute the decision boundary for the Perceptron:

$$
\begin{aligned}
0 & =x_{1} \cdot w_{1}+x_{2} \cdot w_{2}+w_{0} \\
x_{2} \cdot w_{2} & =-x_{1} \cdot w_{1}-w_{0} \\
x_{2} & =-\frac{w_{1}}{w_{2}} \cdot x_{1}-\frac{w_{0}}{w_{2}}
\end{aligned}
$$

The decision boundary is a line:

## Hebb Learning Rule

Weights were learned using the Hebbian learning rule:
"The strength of a synapse increase according to the simultaneous activation of the relative input and the desired target"
(Hebb 1949)
Hebbian learning can be summarized by the following rule:

$$
\begin{aligned}
w_{i}^{n+1} & =w_{i}^{n}+\Delta w_{i} \\
\Delta w_{i} & =\eta \cdot t \cdot x_{i}
\end{aligned}
$$

Where we have

- $\eta$ : learning rate
- $x_{i}$ : the $i^{\text {th }}$ perceptron input
- $t$ : the desired output

## Hebbian Learning of the AND Operator (0)

Suppose we start from a random initialization of $w_{1}=0, w_{2}=1$ and $w_{0}=0$ using a learning rate $\eta=1 / 2$ we get:

## Hebbian Learning of the AND Operator (1)

## Epoch 1

- Record 1:

$$
\begin{aligned}
& \circ \quad w_{1}=0+0=0 \\
& \quad w_{2}=1+0=1 \\
& \quad w_{0}=0-1 / 2=-1 / 2
\end{aligned}
$$

- Record 2:
- $w_{1}=0+0=0$
- $w_{2}=1-1 / 2=1 / 2$
- $w_{0}=-1 / 2-1 / 2=-1$
- Record 3: Ok
- Record 4:

$$
\begin{aligned}
& \circ \quad w_{1}=0+1 / 2=1 / 2 \\
& \circ \quad w_{2}=1 / 2+1 / 2=1 \\
& \circ \quad w_{0}=-1+1 / 2=-1 / 2
\end{aligned}
$$

| $x_{1}$ | $x_{2}$ | $x_{0}$ | $y$ |
| :---: | :---: | :---: | :---: |

$$
\begin{aligned}
& \circ \quad w_{1}=1 / 2+1 / 2=1 \\
& \circ \quad w_{2}=1 / 2+1 / 2=1 \\
& \quad w_{0}=-1+1 / 2=-1 / 2
\end{aligned}
$$

## Hebbian Learning of the AND Operator (3)

Epoch 3

- Record 1: Ok
- Record 2:
- $w_{1}=1+0=1$
- $w_{2}=1-1 / 2=1 / 2$
- $w_{0}=-1 / 2-1 / 2=-1$

| $x_{1}$ | $x_{2}$ | $x_{0}$ | $y$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | -1 |
| 0 | 1 | 1 | -1 |
| 1 | 0 | 1 | -1 |
| 1 | 1 | 1 | 1 |

- Record 3:
- $w_{1}=1-1 / 2=1 / 2$
- $w_{2}=1 / 2-0=1 / 2$
- $w_{0}=-1-1 / 2=-3 / 2$
- Record 4:
- $w_{1}=1 / 2+1 / 2=1$
- $w_{2}=1 / 2+1 / 2=1$
- $w_{0}=-3 / 2+1 / 2=-1$

## Hebbian Learning of the AND Operator (...)

... let's skip some epochs ;) ...

## Hebbian Learning of the AND Operator (7)

Epoch 8

- Record 1: Ok
- Record 2:

| $x_{1}$ | $x_{2}$ | $x_{0}$ | $y$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | -1 |
| 0 | 1 | 1 | -1 |
| 1 | 0 | 1 | -1 |
| 1 | 1 | 1 | 1 |

- $w_{1}=3 / 2-0=3 / 2$
- $w_{2}=3 / 2-1 / 2=1$
- $w_{0}=-3 / 2-1 / 2=-2$
- Record 3: OK
- Record 4: OK

## The XOR Problem

Great, but what if we have a non linearly separable problem?
(i.e., The XOR problem, Minsky '69)

Wait until the '80s and you'll see!

## Topology and Complexity

| Topology | $\begin{gathered} \text { Type of } \\ \text { Decision Region } \\ \hline \end{gathered}$ | XOR Problem | Classes with Meshed Regions | Most General Region Shapes |
| :---: | :---: | :---: | :---: | :---: |
| $\uparrow$ | Half bounded by hyperplanes | (A) (B) <br> (B) (a) |  |  |
|  | Convex Open or Clesed Regions |  |  |  |
|  | Arbitrary Regions (Complexity limited by the number of nodes) | (A) (B) <br> (B) A |  |  |

## Neural Networks - Feedforward Topology -

## Multi-Layer Perceptrons and Artificial Neural Networks

Artificial Neural Network: A set of neurons connected according to a topology

Layer: Neurons at the same distance from the input neurons

Input Layer: Layer of neurons that receives as input the data to process
Output Layer: Layer of neurons that gives the final result of the network

Hidden Layer: Layer of neurons that process data from other neurons to be processed from other neurons

An artificial neural network is a non-linear model characterized by the number of neurons, their topology, activation functions, and the values of synaptic weights and biases.

Lecture Notes on Natural Computation - Matteo Matteucci (matteucci@elet.polimi.it) - p. 23/78

## Learning in Multi Layer Perceptrons: The Idea

Use Gradient Descend to iteratively minimize the network error (it turns out that this was rediscovered many times and named in a different ways):

- Delta Rule
- Widrow Hoff Rule
- Adaline Rule
- Backpropagation

Learning can thus be summarized by the following rule:

$$
\begin{aligned}
\mathbf{w}^{n+1} & =\mathbf{w}^{n}+\Delta \mathbf{w} \\
\Delta \mathbf{w} & =-\eta \cdot \frac{\partial E}{\partial \mathbf{w}}
\end{aligned}
$$

- $\eta$ : learning rate
- $\frac{\partial E}{\partial \mathrm{w}}$ : gradient of the error function w.r.t. the weights

## Learning in Multi Layer Perceptrons: An Example (I)

$$
\begin{aligned}
y & =g\left(\sum_{j}^{J} W_{j} \cdot h\left(\sum_{i}^{I} w_{j i} \cdot x_{i}\right)\right) \\
E & =\sum_{n}^{N}\left(t_{n}-y_{n}\right)^{2}
\end{aligned}
$$

Goal: approximate a target function $t$ given a finite set of $N$ observation
We define some useful variables:

- $a_{j}=\sum_{i}^{I} w_{j i} \cdot x_{i}$ (activation value)
- $b_{j}=h\left(a_{j}\right)$ (output of $j^{\text {th }}$ hidden neuron)
- $A=\sum_{j}^{J} W_{j} b_{j}$

## Learning in Multi Layer Perceptrons: An Example (II)

Given $E=\sum_{n}^{N}\left(t_{n}-y_{n}\right)^{2}=\sum_{n}^{N}\left(t_{n}-g(A)\right)^{2}$

$$
\begin{aligned}
\frac{\partial E}{\partial W_{j}} & =\sum_{n}^{N} 2(t-g(A)) \cdot \frac{\partial}{\partial W_{j}}(t-g(A)) \\
& =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot \frac{\partial}{\partial W_{j}} A \\
& =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot b_{j}
\end{aligned}
$$

We obtain the Backpropagation update rule for $W_{j} \mathrm{~s}$

$$
W_{j}^{t+1}=W_{j}^{t}+2 \eta \sum_{n}^{N}(t-g(A)) \cdot g^{\prime}(A) \cdot b_{j}
$$

## Learning in Multi Layer Perceptrons: An Example (III)

$$
\begin{aligned}
\frac{\partial E}{\partial w_{j i}} & =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot \frac{\partial}{\partial w_{j i}} A \\
& =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot W_{j} \cdot \frac{\partial}{\partial w_{j i}} b_{j} \\
& =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot W_{j} \cdot h^{\prime}\left(a_{j}\right) \frac{\partial}{\partial w_{j i}} a_{j} \\
& =\sum_{n}^{N} 2(t-g(A)) \cdot\left(-g^{\prime}(A)\right) \cdot W_{j} \cdot h^{\prime}\left(a_{j}\right) \cdot x_{i}
\end{aligned}
$$

We obtain the Backpropagation update rule for $w_{j i} \mathrm{~s}$

$$
w_{j i}^{t+1}=w_{j i}^{t}+2 \eta \sum_{n}^{N}(t-g(A)) \cdot g^{\prime}(A) \cdot W_{j} \cdot h^{\prime}\left(a_{j}\right) \cdot x_{i}
$$

## Artificial Neural Network Demo

Stolen from:
http://www.obitko.com/tutorials/neural-network-prediction/function-prediction.html

## Learning in Multi Layer Perceptrons: Regression (I)

$$
y=g\left(\sum_{j}^{J} W_{j} \cdot h\left(\sum_{i}^{I} w_{j i} \cdot x_{i}\right)\right)
$$

Goal: approximate a target function $t$ given a finite set of $N$ observation

$$
t_{n}=y_{n}+\epsilon_{n} \quad \epsilon \sim N\left(0, \sigma^{2}\right) \quad \rightarrow \quad t_{n} \sim N\left(y_{n}, \sigma^{2}\right)
$$

Thus we have a sample $\mathbf{t}_{1}, \mathbf{t}_{2}, \ldots \mathbf{t}_{N}$ of i.i.d. observations from $N(\mathbf{y}, \boldsymbol{\Sigma})$
Learning in Artificial Neural Networks $\Rightarrow$ Maximum Likelihood Estimation

## Learning in Multi Layer Perceptrons: Regression (II)

We have a sample $t_{1}, t_{2}, \ldots t_{N}$ of i.i.d. observations from $N\left(y, \sigma^{2}\right)$; define the Likelihood $L$ of the sample as its probability (suppose $k=1$ )

$$
L(\mathbf{w})=\prod_{n}^{N} \frac{1}{\sqrt{2 \pi} \sigma} e^{-\frac{1}{2 \sigma^{2}}\left(t_{n}-y_{n}\right)^{2}}
$$

Look for the set of weights that maximize it

$$
\begin{aligned}
\arg \max _{\mathbf{w}} L(\mathbf{w}) & =\arg \max _{\mathbf{w}} \sum_{n}^{N}\left[\log \frac{1}{\sqrt{2 \pi} \sigma}-\frac{1}{2 \sigma^{2}}\left(t_{n}-y_{n}\right)^{2}\right] \\
& =\arg \max _{\mathbf{w}}-\sum_{n}^{N} \frac{1}{2 \sigma^{2}}\left(t_{n}-y_{n}\right)^{2} \\
& =\arg \min _{\mathbf{w}} \sum_{n}^{N}\left(t_{n}-y_{n}\right)^{2}
\end{aligned}
$$

## Learning in Multi Layer Perceptrons: Classification (I)

$$
y=g\left(\sum_{j}^{J} W_{j} \cdot h\left(\sum_{i}^{I} w_{j i} \cdot x_{i}\right)\right)
$$

Goal: separate two (or more) classes $\Omega_{0}, \Omega_{1}$ according to the posterior probability (this time $t=1$ if $t \in \Omega_{1}$ and $t=0$ if $t \in \Omega_{0}$ )

$$
p(t \mid \mathbf{x})=y^{t}(1-y)^{1-t} \quad \rightarrow \quad t \sim B e(y)
$$

Thus we have a sample $\mathbf{t}_{1}, \mathbf{t}_{2}, \ldots \mathbf{t}_{N}$ of i.i.d. observations from a Bernulli

Learning in Artificial Neural Networks $\Rightarrow$ Maximum Likelihood Estimation

## Learning in Multi Layer Perceptrons: Classification (II)

We have a sample $t_{1}, t_{2}, \ldots t_{N}$ of i.i.d. observations from a Bernoulli distribution define the Likelihood $L$ of the sample as its probability

$$
L(\mathbf{w})=\prod_{n}^{N} y_{n}^{t_{n}}\left(1-y_{n}\right)^{1-t_{n}}
$$

Look for the set of weights that maximize it

$$
\begin{aligned}
\arg \max _{\mathbf{w}} L(\mathbf{w}) & =\arg \max _{\mathbf{w}} \sum_{n}^{N} t_{n} \log y_{n}+\left(1-t_{n}\right) \log \left(1-y_{n}\right) \\
& =\arg \min _{\mathbf{w}}-\sum_{n}^{N} t_{n} \log y_{n}+\left(1-t_{n}\right) \log \left(1-y_{n}\right)
\end{aligned}
$$

Note: this is called cross entropy and its minimization is equivalent to the minimization of the Kullback-Leibler divergence of the network output and the target distribution

## Issues in Learning Artificial Neural Networks

- Improving Convergence
- Gradient Descend with Momentum
- Quasi Newton Methods
- Conjugate Gradient Methods
- ...
- Local Optima
- Multiple Restarts
- Randomized Algorithms
- ...
- Generalization and Overfitting
- Early Stopping
- Weight Decay

Let's focus on generalization and overfitting!

## Generalization \& Overfitting

Overfitting: we have overfitting when the model we learnt fits the noise in the data, thus it does not generalize on new samples (it just memorizes the training set).

Can we measure generalization?

1. Hide some data before learning the model(Test Set)
2. Estimate how well the model predict on "new" data (Test Set Error)

Can we avoid overfitting?

- Use cross-validation techniques
- Use statistical bias on the model space

General rule: Use Occam's razor!
"Entia non sunt multiplicanda praeter necessitatem"

## Improving Generalization: Early Stopping

We would like to stop the learning process (a.k.a. optimization routine) before the model starts to fit the noise in the data

This is usually a good method to find out how many neurons we need in the hidden layer: compare different topologies w.r.t. the validation error.

## Improving Generalization: Weight Decay (I)

Up to now, we have used Maximum Likelihood Estimation for the weights:

$$
\hat{\mathbf{w}}=\arg \max _{\mathbf{w}} P(\mathcal{D} \mid \mathbf{w})
$$

If we use a Bayesian approach, we can use Maximum A-Posteriori:

$$
\hat{\mathbf{w}}=\arg \max _{\mathbf{w}} P(\mathbf{w} \mid \mathcal{D})=\arg \max _{\mathbf{w}} P(\mathcal{D} \mid \mathbf{w}) P(\mathbf{w})
$$

(We "just" need a prior distribution $P(\mathbf{w})$ for the network weights)
From theoretical consideration and empirical results we get:

- Use conjugate priors to get an "easy" posterior distribution
- Small weights improve network generalization capabilities

$$
w \sim N\left(0, \sigma_{w}^{2}\right)
$$

## Improving Generalization: Weight Decay (II)

$$
\begin{aligned}
\hat{\mathbf{w}} & =\arg \max _{\mathbf{w}} P(\mathcal{D} \mid \mathbf{w}) P(\mathbf{w}) \\
& =\arg \max _{\mathbf{w}} \prod_{n}^{N} \frac{1}{\sqrt{2 \pi} \sigma} e^{-\frac{1}{2 \sigma^{2}}\left(t_{n}-y_{n}\right)^{2}} \cdot \prod_{m}^{M} \frac{1}{\sqrt{2 \pi} \sigma_{w}} e^{-\frac{1}{2 \sigma_{w}^{2}}\left(0-w_{m}\right)^{2}} \\
& =\arg \min _{\mathbf{w}} \sum_{n}^{N} \frac{1}{2 \sigma^{2}}\left(t_{n}-y\right)^{2}+\sum_{m}^{M} \frac{1}{2 \sigma_{w}^{2}} w^{2} \\
& =\arg \min _{\mathbf{w}} \sum_{n}^{N}\left(t_{n}-y\right)^{2}+\gamma \sum_{m}^{M} w^{2}
\end{aligned}
$$

This way we penalize "network complexity" introducing a bias

## Neural Networks <br> - Radial Basis Functions -

## Radial Basis Approximation

Consider the following function approximation:

$$
\hat{f}(\mathbf{x})=w_{0}+\sum_{u=1}^{U} w_{u} \cdot K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)
$$

Where we have:

- $\mathbf{x}_{u}$ is an instance from $\mathbf{X}$
- $K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)$ is called Kernel function and it is defined so that it decrease as the distance $d\left(\mathbf{x}_{u}, \mathbf{x}\right)$ increase
$\hat{f}(\mathrm{x})$ is a global approximation of $f(\mathrm{x})$ obtain from the local contributions of $\mathbf{x}_{u} s$ and it is possible approximate any function with arbitrarily small error, provided a sufficiently large number $U$ of radial basis functions.

## Radial Basis Functions

Consider to use a Gaussian function as Kernel

$$
K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)=e^{-\frac{1}{2 \sigma^{2}} d^{2}\left(\mathbf{x}_{u}, \mathbf{x}\right)} .
$$

We can rewrite the radial bases approximation as a two layer artificial neural network (called Radial Basis Function):

$$
y=w_{0}+\sum_{u=1}^{U} w_{u} \cdot e^{-\frac{1}{2 \sigma^{2}} d^{2}\left(\mathbf{x}_{u}, \mathbf{x}\right)}
$$

## Learning with Radial Basis Functions

Radial Basis Function are typically trained in a two stage process:

1. The number $U$ of hidden units is determined and each hidden unit is defined by choosing the values of $\mathbf{x}_{u}$ and $\sigma_{u}^{2}$ that define its kernel function $K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)$
2. The weights $w_{u}$ are trained to maximize the fitting of the network using the error function

$$
E=\frac{1}{2} \sum_{n}^{N}\left(f\left(\mathbf{x}_{n}\right)-\hat{f}\left(\mathbf{x}_{n}\right)\right)^{2}
$$

Since the kernel functions are held fixed during the second stage, the linear weights $w_{u}$ can be trained very efficiently!

## Linear Regression to Learn the Weighs (I)

According to the RBF model we can consider the network output $\mathbf{Y}$ as a linear combination of hidden neurons output U :

$$
\mathbf{Y}=\mathbf{U w}
$$

Learning is thus the solution of $N$ linear equations in $U$ unknowns that we can write using matrix notation:

$$
\left|\begin{array}{c}
t_{1} \\
t_{2} \\
\vdots \\
t_{N}
\end{array}\right|=\left|\begin{array}{cccc}
h\left(\sum_{i}^{I} w_{1 i} x_{i}\right)_{1} & h\left(\sum_{i}^{I} w_{2 i} x_{i}\right)_{1} & \cdots & h\left(\sum_{i}^{I} w_{U i} x_{i}\right)_{1} \\
h\left(\sum_{i}^{I} w_{1 i} x_{i}\right)_{2} & h\left(\sum_{i}^{I} w_{2 i} x_{i}\right)_{2} & \cdots & h\left(\sum_{i}^{I} w_{U i} x_{i}\right)_{2} \\
\vdots & \vdots & \vdots & \vdots \\
h\left(\sum_{i}^{I} w_{1 i} x_{i}\right)_{N} & h\left(\sum_{i}^{I} w_{2 i} x_{i}\right)_{N} & \cdots & h\left(\sum_{i}^{I} w_{U i} x_{i}\right)_{N}
\end{array}\right| \cdot\left|\begin{array}{c}
w_{1} \\
w_{2} \\
\vdots \\
w_{U}
\end{array}\right|
$$

$$
[N \times 1]=[N \times U] \cdot[U \times 1]
$$

## Linear Regression to Learn the Weighs (II)

Suppose we have no noise, exact model and well-conditioned U matrix we can obtain a closed form for the solution (note we cannot invert directly U since it could be not invertible):

$$
\begin{aligned}
\mathbf{Y} & =\mathbf{U w} \\
\mathbf{U}^{\prime} \mathbf{Y} & =\mathbf{U}^{\prime}(\mathbf{U w}) \\
\mathbf{U}^{\prime} \mathbf{Y} & =\left(\mathbf{U}^{\prime} \mathbf{U}\right) \mathbf{w} \\
\left(\mathbf{U}^{\prime} \mathbf{U}\right)^{-1} \mathbf{U}^{\prime} \mathbf{Y} & =\left(\mathbf{U}^{\prime} \mathbf{U}\right)^{-1}\left(\mathbf{U}^{\prime} \mathbf{U}\right) \mathbf{w} \\
\left(\mathbf{U}^{\prime} \mathbf{U}\right)^{-1} \mathbf{U}^{\prime} \mathbf{Y} & =\mathbf{w}
\end{aligned}
$$

This is not iterative! It could be computationally intensive, but "years" of linear algebra have discovered efficient solutions for computing $\left(\mathbf{U}^{\prime} \mathbf{U}\right)^{-1}$ even with ill-conditioned matrixes ... check out for that on:

Numerical recipes in Fortran/C/C++

## Radial Basis Function Demo

http://lcn.epfl.ch/tutorial/english/rbf/html/index.html

## Setting Up the Kernels

We can find different approaches for the choice of the kernel functions:

1. Allocate a Gaussian kernel function for each training example $<\mathbf{x}_{n}, f\left(\mathbf{x}_{n}\right)>$ centering it at $\mathbf{x}_{n}$ and assigning some width $\sigma^{2}$.

- Global approximation from local interactions of data points
- Good fitting of the training data, but you'll have problems with overfitting and performance

2. Use a relatively small $U$, place neurons according to the input density, i.e. using some clustering algorithm

- Faster that using a kernel function for each data point
- Improved generalization capabilities, however it does not consider the output values in the training set

3. Use a relatively small $U$, place one neuron at the time, train the network and place a new neuron on the record with the higher prediction error.

- Good generalization, relatively fast and easy to implement

## Normalized Radial Basis Functions (NRBF)

Radial Basis function can be normalized using the softmax function

$$
\bar{K}_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)=\operatorname{softmax}\left(K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)\right)=\frac{K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}{\sum_{u} K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}
$$

$\operatorname{blu}(0.3,0.001), \quad \operatorname{red}(0.5,0.001), \quad \operatorname{black}(0.7,0.001)$

## Normalized Radial Basis Functions (NRBF)

Radial Basis function can be normalized using the softmax function

$$
\bar{K}_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)=\operatorname{softmax}\left(K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)\right)=\frac{K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}{\sum_{u} K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}
$$

$\operatorname{blu}(0.3,0.002), \quad \operatorname{red}(0.5,0.002), \quad \operatorname{black}(0.7,0.002)$

## Normalized Radial Basis Functions (NRBF)

Radial Basis function can be normalized using the softmax function

$$
\bar{K}_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)=\operatorname{softmax}\left(K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)\right)=\frac{K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}{\sum_{u} K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}
$$

$\operatorname{blu}(0.3,0.008), \quad \operatorname{red}(0.5,0.008), \quad \operatorname{black}(0.7,0.008)$

## Normalized Radial Basis Functions (NRBF)

Radial Basis function can be normalized using the softmax function

$$
\bar{K}_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)=\operatorname{softmax}\left(K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)\right)=\frac{K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}{\sum_{u} K_{u}\left(d\left(\mathbf{x}_{u}, \mathbf{x}\right)\right)}
$$

blu( $0.3,0.0009), \quad \operatorname{red}(0.5,0.008), \quad$ black $(0.7,0.015)$

## Neural Networks <br> - Recurrent Architectures -

## Neural Networks for Dynamical Systems

A new Task: we want to predict the next day stock market average $y(t+1)$ based on the current day's economic indicators $\mathbf{x}(t)$

We have mainly three approaches to do that with artificial neural networks:

- Standard Feedforward: we can do regression from $\mathbf{x}(t)$ to $y(t+1)$, but we cannot capture dependencies on earlier values of $x$
- Feedforward with Delayed Input: we can replicate a finite number of earlier values of $\mathbf{x}$ and apply regression from $[\mathbf{x}(t) \mathbf{x}(t-1) \ldots \mathbf{x}(t-q)]$, but we do not know how much is $q$
- Recurrent Artificial Neural Networks: we can add a new unit $b$ to the hidden layer and a new input unit $c(t)$ to represent the value of $b$ at time $(t-1)$. $b$ thus can summarize information from earlier values of x arbitrarily distant in time.

## Feedforward with Delayed Input

| $x(t)$ | $y(t)$ |
| :---: | :---: |
| 1 | 7 |
| 2 | 6 |
| 3 | 7 |
| 4 | 8 |
| 5 | 9 |
| 6 | 5 |

How can we learn the weights for this kind of network?

- Build-up a delayed dataset from the original one
- Use the standard backpropagation learning algorithm

$$
y(t+1)=g\left(\sum_{j}^{J} W_{j} \cdot h\left(\sum_{i=0}^{T} w_{j i} \cdot x(t-i)\right)\right)
$$

## Recurrent Artificial Neural Networks

1. Recurr the output as input (network output $\rightarrow$ equilibrium)
2. Recurr the output (and its previous values) as input
3. Recurr the internal (hidden) state of the network as input

## Finding Structure in Time (Elman Networks)

How can we learn the weights for this kind of networks?

## Backpropagation Through Time (Elman Networks)

1. Perform "network unfolding"

2. Approximate backpropagation by:

- Use a finite number unwrapping steps $U$
- Take the average of weigths over time: $v_{j b}=\frac{1}{U} \sum_{u}^{U} v_{j b}(t-u)$
- Compute the sum of gradients over time: $\frac{\partial E}{\partial v_{j b}}=\sum_{u}^{U} \frac{\partial E}{\partial v_{j b}(t-u)}$

## Neural Networks - Neuro-Fuzzy Networks -

## Neuro vs Fuzzy Modeling

Both Neural Networks and Fuzzy Rules are non-linear modeling paradigms robust with respect to uncertanty (noise) in the data. In theory, they are equivalent, yet in practice each has its own pros and cons:

- Neural networks
- Knowledge automatically acquired from experience $\rightarrow$ good :)
- No explanation on what's going on in the black-box $\rightarrow$ bad :(
- No way to extract/integrate structural knowledge $\rightarrow$ bad :(
- Fuzzy rules
- Reasoning on imprecise information $\rightarrow$ good :)
- Clear understanding of the inference mechanism $\rightarrow$ good :)
- No way of learning experience directly from data $\rightarrow$ bad :(

Can we get the best of the two worlds from a single (hybrid) system?
Can we extend neural network to extract fuzzy rules from data?

## Neural Learning of Sugeno-Type Fuzzy Inference (I)

Suppose we have the the fuzzy system having rules in the form:

$$
R_{j}: \text { if } x_{1} \text { is } A_{j 1} \wedge x_{2} \text { is } A_{j 2} \wedge \ldots \wedge x_{I} \text { is } A_{j I} \text { then } y=z_{j}
$$

Being $A_{j i}$ fuzzy numbers of triangular form and $z_{j}$ real numbers, the system can be represented as a non-linear mapping:

$$
y=f(\mathbf{x})=f\left(x_{1}, \ldots x_{I}\right)
$$

- Define the firing level of $j^{\text {th }}$ rule by the Larsen's product operator (or any other t-norm for the and operator): $\alpha_{j}=\prod_{i=1}^{I} A_{j i}\left(x_{i}\right)$
- The output of the system is thus defined as: $y=\frac{\sum_{j} \alpha_{j} z_{j}}{\sum_{j} \alpha_{j}}$

Can we learn the shapes of fuzzy numbers $A_{j i}$ and output $z_{j}$ from $\underline{\underline{\text { experience }} \mathcal{D}}=\left\{(\mathrm{x}, t)_{1}, \ldots,(\mathrm{x}, t)_{n}, \ldots,(\mathrm{x}, t)_{N}\right\}$ ?

## Neural Learning of Sugeno-Type Fuzzy Inference (II)

To better understand how this is related to neural networks and learning consider a simplified example.

- Suppose we have a system formed by just two rule with two input and one output variable:

$$
\begin{aligned}
& R_{1}: \quad \text { if } x_{1} \text { is } A_{1} \wedge x_{2} \text { is } A_{2} \text { then } y=z_{1} \\
& R_{2}: \text { if } x_{1} \text { is } A_{2} \wedge x_{2} \text { is } A_{1} \text { then } y=z_{2}
\end{aligned}
$$

with fuzzy terms $A_{1}$ (small) and $A_{2}$ (big) having a sigmoidal membership function defined by: $A_{k}(x)=\frac{1}{1+\exp \left(b_{k}\left(x-a_{k}\right)\right)}$.

- Define now a three new special neurons ...

1. $P($.$) : performing the Product of its input$
2. $S($.$) : performing the Sum of its input$
3. $R($.$) : performing the Ratio of its input$

Here it is your first Fuzzy-Neural Network ... o well on the next slide ;)

## Neural Learning of Sugeno-Type Fuzzy Inference (III)

$$
\begin{aligned}
y & =\sum_{j=1}^{2} \frac{z_{j} \cdot \alpha_{j}}{\alpha_{1}+\alpha_{2}} \\
& =\frac{z_{1} \cdot \alpha_{1}+z_{2} \cdot \alpha_{2}}{\alpha_{1}+\alpha_{2}}
\end{aligned}
$$

Now you got the idea, all remains to do is learning $z_{j}, a_{k}$ and $b_{k}$ so let's:

1. Define your favourite Error measure over the training samples:

$$
E=\frac{1}{2} \sum_{n}^{N}\left(y_{n}-t_{n}\right)^{2}
$$

2. Run your fashioned steepest descend optimization package on the network ... or do it by hand!

## Neural Learning of Sugeno-Type Fuzzy Inference (IV)

$$
\begin{gathered}
\frac{\partial E}{\partial z_{j}}=\frac{\partial}{\partial z_{j}} \frac{1}{2} \sum_{n}^{N}\left(y_{n}-t_{n}\right)^{2}=\sum_{n}^{N}\left(\left(y_{n}-t_{n}\right) \frac{\partial y_{n}}{\partial z_{j}}\right)=\sum_{n}^{N}\left(\left(y_{n}-t_{n}\right) \frac{\alpha_{j}\left(\mathbf{x}_{n}\right)}{\sum_{j} \alpha_{j}\left(\mathbf{x}_{n}\right)}\right) \\
\frac{\partial E}{\partial a_{i}}=\frac{\partial}{\partial a_{i}} \frac{1}{2} \sum_{n}^{N}\left(y_{n}-t_{n}\right)^{2}=\sum_{n}^{N}\left(\left(y_{n}-t_{n}\right) \frac{\partial y_{n}}{\partial a_{i}}\right)=\ldots \\
\frac{\partial E}{\partial b_{i}}=\frac{\partial}{\partial b_{i}} \frac{1}{2} \sum_{n}^{N}\left(y_{n}-t_{n}\right)^{2}=\sum_{n}^{N}\left(\left(y_{n}-t_{n}\right) \frac{\partial y_{n}}{\partial b_{i}}\right)=\ldots
\end{gathered}
$$

In 1993 R. Jang showed that fuzzy inference systems with simplified fuzzy rules (i.e., having crisp outputs) are universal approximators. The more fuzzy terms and rules are used, the closer is the output of the fuzzy system to the desired one.

Does this remind you about anything?

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (I)

Consider now a more complex example using the following fuzzy rules:

$$
\begin{array}{ll}
R_{1}: & \text { if } x_{1} \text { is } L_{1} \wedge x_{2} \text { is } L_{2} \wedge x_{3} \text { is } L_{3} \text { then } y=V B \\
R_{2}: & \text { if } x_{1} \text { is } H_{1} \wedge x_{2} \text { is } H_{2} \wedge x_{3} \text { is } L_{3} \text { then } y=B \\
R_{3}: & \text { if } x_{1} \text { is } H_{1} \wedge x_{2} \text { is } H_{2} \wedge x_{3} \text { is } H_{3} \text { then } y=S
\end{array}
$$

Being $x_{1}, x_{2}, x_{3}$ the exchange rates USD vs DEM, USD vs SEK, and USD vs FIM, we obtain:
$R_{1}$ if the USD is weak against DEM, SEK, and FIM then our portfolio value is very big
$R_{2}$ if the USD is strong against DEM, SEK, and USD is weak against FIM then our portfolio value is big
$R_{3}$ if the USD is strong against DEM, SEK, and FIM then our portfolio value is small big

Note: this was a pre-Euro Swedish example :)

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (II)

Define the fuzzy sets for the input and output variables:

- LOW is $L_{i}(x)=\frac{1}{1+\exp \left(b_{i}\left(x-c_{i}\right)\right)}$
- HIGH is $H_{i}(x)=1-L_{i}(x)=\frac{1}{1+\exp \left(-b_{i}\left(x-c_{i}\right)\right)}$
- VERY_SMALL is $V S(x)=\frac{1}{1+\exp \left(b_{S}\left(x-c_{S}-c_{V}\right)\right)}$
- VERY_BIG is $V B(x)=1-V S(x)=1-\frac{1}{1+\exp \left(b_{S}\left(x-c_{S}-c_{V}\right)\right)}$
- SMALL is $S(x)=\frac{1}{1+\exp \left(b_{S}\left(x-c_{S}\right)\right)}$
- BIG is $B(x)=1-S(x)=1-\frac{1}{1+\exp \left(-b_{S}\left(x-c_{S}\right)\right)}$

Let's evaluate the daily portfolio value by Tsukamoto's reasoning:

1. The firing level is obtained by: $\alpha_{j}=L_{1}\left(x_{1}\right) \wedge L_{2}\left(x_{2}\right) \wedge L_{3}\left(x_{3}\right)$.
2. The output is derived: $z_{j}=$ FuzzySet $^{-1}\left(\alpha_{j}\right)$
3. The overall output is composed: $y=\frac{\sum_{j} \alpha_{j} \cdot z_{j}}{\sum_{j} \alpha_{j}}$

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (III)

Let's evaluate the first rule by Tsukamoto's reasoning:

1. The firing level is obtained by: $\alpha_{1}=L_{1}\left(x_{1}\right) \wedge L_{2}\left(x_{2}\right) \wedge L_{3}\left(x_{3}\right)$.
2. The output is derived: $z_{1}=V B^{-1}\left(\alpha_{j}\right)=c_{S}+c_{V}+\frac{1}{b_{B}} \ln \frac{1-\alpha_{1}}{\alpha_{1}}$
3. The overall output is composed: $y=\frac{\alpha_{1} \cdot z_{1}+\alpha_{3} \cdot z_{2}+\alpha_{3} \cdot z_{3}}{\alpha_{1}+\alpha_{2}+\alpha_{3}}$

Let's put it in a neural network!

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Layer 1: The output of the nodes is the degree to which the give input satisfies the linguistic label

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Layer 2: Each node computes the firing strength of the associated rule (rule nodes) using a t-norm operator

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Layer 3: Nodes labeled $N($.$) perform a normalization of firing level$ $\beta_{j}=\frac{\alpha_{j}}{\sum_{j} \alpha_{j}}$. Others compute rule output (i.e., $z_{1}=V B^{-1}\left(\alpha_{1}\right)$ )

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Layer 4: Node in this layer compute the product of the normalized strength $\beta_{j}$ and the rule output $z_{j}$

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Layer 5: The single node in this layer computes the overall system output as the sum of all incoming signals $y=\sum_{j} z_{j}$

## Adaptive Neuro-Fuzzy Inference System [ANFIS] (IV)

Now you know the trick! Plug you best backpropagation algorithm and learn your brand new Adaptive Neuro Fuzzy Inference System from data!

## The Neuro-Fuzzy Trick Explained

Given a rule set:

$$
R_{j}: \text { if } x_{1} \text { is } A_{j 1} \wedge x_{2} \text { is } A_{j 2} \wedge \ldots \wedge x_{I} \text { is } A_{j I} \text { then } y=z_{j}
$$

We can write a closed form to express its output as a non-linear mapping:

$$
y=f(\mathbf{x})=f\left(x_{1}, \ldots x_{I}\right)
$$

If this form is differentiable then it is possible to minimize and error function (e.g., sum of squared errors) by gradient descend as with neural networks:

$$
\theta^{t+1}=\theta^{t}-\eta \frac{\partial E(f, \mathcal{D})}{\partial \theta}
$$

But only if we use differentiable t-norm, t-conorm, and inference!

## Neural Networks - Self Organizing Maps -

## Self Organizing Features Maps: The Task

Kohonen Self Organizing Features Maps (a.k.a SOM) provide a way to represent multidimensional data in much lower dimensional spaces.

- They implement a data compression technique similar to vector quantization
- They store information in such a way that any topological relationships within the training set are maintained

Example: Mapping of colors from their three dimensional components (i.e., red, green and blue) into two dimensions.

Lecture Notes on Natural Computation - Matteo Matteucci (matteucci@elet.polimi.it) - p. 73/78

## Self Organizing Features Maps: The Topology

- The network is a lattice of 'nodes', each of which is fully connected to the input layer
- Each node has a specific topological position and contains a vector of weights of the same dimension as the input vectors
- There are no lateral connections between nodes within the lattice

A SOM does not need a target output to be specified; instead, where the node weights match the input vector, that area of the lattice is selectively optimized to more closely resemble the data vector

## Self Organizing Features Maps: The Algorithm

Training occurs in several steps over many iterations:

1. Initialize each node's weights
2. Presented a random vector from the training set to the lattice
3. Examinate every node to calculate which one's weights are most like the input vector (the winning node is commonly known as the Best Matching Unit)
4. Calculate the radius of the neighborhood of the BMU (this is a value that starts large, typically set to the 'radius' of the lattice, but diminishes each time-step), any nodes found within this radius are deemed to be inside the BMU's neighborhood
5. Each neighboring node's weights are adjusted to make them more like the input vector. The closer a node is to the BMU, the more its weights get altered
6. Repeat step 2 for N iterations

## Practical Learning of Self Organizing Features Maps

There are few things that have to be specified in the previous algorithm:

- Choosing the weights initialization
- We select the Best Matching Unit according to its the weight distance from the input vector:

$$
\left\|\mathbf{x}-\mathbf{w}_{i}\right\|=\sqrt{\sum_{k=1}^{p}\left(\mathbf{x}[k]-\mathbf{w}_{i}[k]\right)^{2}}
$$

- Select the neighborhood according to some decreasing function

$$
h_{i j}=e^{-\frac{(i-j)^{2}}{2 \sigma^{2}}}
$$

- Define the updating rule
$\mathbf{w}_{i}(t+1)= \begin{cases}\mathbf{w}_{i}+\alpha(t)\left[\mathbf{x}(t)-\mathbf{w}_{i}(t)\right], & i \in N_{i}(t) \\ \mathbf{w}_{i}, & i \notin N_{i}(t)\end{cases}$
