Sensors & Actuators

Matteo Matteucci matteo.matteucci@polimi.it

Artificial Intelligence and Robotics Lab - Politecnico di Milano

## What does it make an autonomous robot?

Sensors perceive:

- Internal state of the robot (proprioceptive sensors)
- External state of the environment (exterocemptive sensors)

Effectors modify the environment state

• Match the robot task (e.g., wheels, legs, grippers)

Actuators enable effectors to act

• E.g., passive actuation, motors of various types

## **Type of Actuators**

Actuators enable effectors to act

- Electric motors
- Hydraulics
- Pneumatics
- Photo-reactive materials
- Chemically reactive materials
- Thermally reactive materials
- Piezoelectric materials

## **Most Popular Actuators**

First robots used hydraulic and pneumatic actuators

- Hydraulic actuators are expensive, weighing, and hard to maintain (big robots)
- Pneumatic actuators are used for stop-to-stop applications such as pick-and-place (fast actuation)

Nowadays most common actuators are electrical motors

- Each joint has usually its own motor (and controller)
- High speed motors are reduced by (elastic) gearing
- They need internal sensors to be controlled
- Stepper motors do not need internal sensors, but when an error occurs their position is unknown

## **DC Motors**

Direct Current (DC) motors

- Convert electrical energy into mechanical energy
- Small, cheap, reasonably efficient, easy to use

How do they work?

- Electrical current traverses loops of wires mounted on a rotating shaft
- Loops of wire generate a magnetic field which reacts against the magnetic fields of permanent magnets placed around
- These two magnetic fields push against one another and the armature turns

#### **DC Motors**

POLITECNICO MILANO 1863

## **DC Motors: Brushed and Brushless Motors**

Brushes used to change magnetic polarity, they're cheap but ...

- Brushes eventually wear out
- Brushes make noise
- Limit the maximum speed
- Hard to cool
- Limit the number of poles

Brushless motors overcome these problems but they are more expensive

- Brushes are replaced by computer
- Permanent magnets on the rotor
- Electromagnets on the stator

## **Stepper motors**

A <u>stepper motor</u> is a brushless, synchronous electric motor that converts digital pulses into mechanical shaft rotations.

Rotation angle proportional to input pulse Full torque at standstill (energized windings) Precise positioning and repeatability Response to starting/stopping/reversing Very reliable (no contact brushes) Allow open-loop control (simpler and cheaper) Allow very low speed synchronous rotation with a load directly coupled to the shaft. Wide range of rotational speeds Require a dedicated control circuit Use more current than D.C. motors Torque reduces at higher speeds Resonances can occur if not properly controlled. Not easy to operate at extremely high speeds

#### **Servo Motors**

"Servo": specialized motors that can move their shaft to a specific position

- Used in hobby radio control applications
- Measure their own position and compensate for external loads when corresponding to a control signal

#### Servo motors are built from DC motors by adding

- Gear reduction
- Position sensor
- Control electronics

Shaft travel is restricted to 180 degrees but it is enough for most applications

## Sensors

Sensors allow a robot to accomplish complex tasks autonomously

Two main categories

- Internal sensors (proprioceptive)
- External sensors (exteroceptive)

## Other classification

 Passive (measure physical property) vs Active sensors (emitter + detector)

#### Encoders

An encoder converts motor/joint rotary motion or position into electronic pulses

Linear encoders

 Consist of a long linear read track, together with a compact read head

### Rotary encoders

- Both for rotary and linear motion (in conjunction with some mechanism) convert rotary motion into electrical signals
- They can be incremental or absolute

#### **Incremental rotary encoders**

It is based on the photoelectric principle

- A disk with two traces (or sensors) where transparent and opaque zones alternate
- The two traces allows to identify rotation direction and increases resolution (quadrature)

# Quadrature technique

- The two signals are shifted by ¼ step
- N, is the number of steps, i.e., the number of light/dark zones, per turn
- Resolution is 360°/4N
  - CCW: 11 is followed by 10
  - CW: 1 1 is followed by 0 1

#### **Absolute rotary encoders**

The disk econdes a position

- Transparent and opaque areas on concentric rings
- For an N-bit word there are N rings
- Absolute resolution: 360°/2<sup>N</sup>
- In robotic applications at least 12 rings are used (360°/4096)
- Binary codes with single variations, i.e., Gray code, are used to avoid abiguities

## **Distance perception: time-of-flight telemeter**

It measures the time between the emitter produces the signal and the detector receives its reflection

- Distance covered by the signal is 2d
- Time of flight is  $\Delta T = 2d/c$

Acoustic waves are used (although light is possible)

- Low speed: v=340 m/s
- Low directionality: 20 40°
- Polaroid ultrasonic sensors (sonar)
  - range 0.3 10m
  - accuracy 0.025m
  - cone opening 30°
  - frequency 50 KHz

The signal is largely affected by noise with significant reflections ...

#### **Issues with sonars**

far away

Soft objects

Rooms may look larger than expected at corners!

soft

#### **Distance perception: reflective optosensors**

Reflective optosensors are active sensors (e.g., SHARP IR Sensors)

- Emitter: a source of light, e.g., LED (light emitter diode) or IR (infra red)
- Detector: a light detector, e.g., photodiode or phototransistor

It uses triangulation to compute distance

- Emitter casts a beam of light on the surface
- The detector measures the angle corresponding to the maximum intensity of returned light
- Being s the distance between the emitter and the detector

$$d = s \cdot \tan \alpha$$

#### **Issues with reflective optosensors**

Infrared sensors are relatively cheap and robust but ...

- Non linear characteristics which need to be calibrated
- Have an ambiguity for short range (should be placed in the robot)
- Have fixed ranges / opening angles (requires proper selection)
- May suffer reflections ... sometimes

## **Distance Perception: Kinect**

Kinect is a motion sensing input device built by Microsoft (Primesense) for Xbox 360

- 3D scanner
  - Infrared projector
  - Infrared camera (11-bit 640x480)
  - Range 1.2 3.5 m (up to 0.7-6 m)
  - Angular field of view: 57° h, 43° v
- 30Hz 8-bit RGB camera (640x480)

## **Distance perception: time-of-flight camera**

#### 3D time-of-flight (TOF) cameras

- Illuminate the scene with a modulated light source and observe reflected light
- Phase shift between illumination and reflection is translated to distance

Some issues exist with these sensors

- Illumination is from a solid-state laser or a near-infrared (~850nm) LED
- An imaging sensor receives the light and converts the photonic energy to electrical current
- Distance information is embedded in the reflected component. Therefore, high ambient component reduces the signal to noise ratio (SNR).

### **Distance perception: Laser Range Finder**

Lasers are definitely more accurate sensors

- 180 ranges over 180° (up to 360°)
- 1 to 64 planes scanned
- 10-75 scans/second
- <1cm range resolution</p>
- Max range up to 50-80 m
- Problems only with mirrors, glass, and matte black.

~ 40.000 €

The LD Laser Scanner:

Return beam

Laser beam

Laser diode

Photo diode

## **Position sensors (outdoor)**

Outdoor position can be measure by a Global Navigation Satellite System

• Several constellations exist (GPS, GLONASS, Beidou, Galileo, ...)

Global Positioning System (GPS)

- 24 satellites orbit the Earth twice a day
- They synchronously emit location and time
- Receiver compares transmitted and arrival times
- At least 4 sensors must be perceived
- Accuracy is about 2.5m@2Hz (20 cm DGPS)

Several issues

- Do not work indoor, underwater, or in urban canyon
- Need line of sight reception
- Suffer multiple paths and reflections

## **Inertial sensor**

Gyroscopes

Angular velocities

Accelerometers

- Linear accelerations
- Gravitational vector

Magnetometers/compass

• Earth magnetic field vector

An Inertial Measurement Unit (IMU) fuses gyroscopes, accelerometers and magnetometers to provide full 6DoF pose estimate

Intertial measurements integration (e.g., to compute position) cumulate errors and drifts significantly over time, especially with cheap MEMS technology ...

ST-124 Inertial Guidance Platform used in the Saturn V, 1960s

## **Tactile Sensors**

These sensors are used for manipulation purposes

# Two main categories

- Binary
  - realized by switches
  - placed on the fingers of a manipulator
  - may be arranged in arrays (bumpers)
  - on the external side to avoid obstacles
- Analogical (real valued)
  - soft devices that produce a signal proportional to the local force
  - a spring coupled with a shaft
  - soft conductive material that change resistance with compression
  - measure also movements tangential to the sensor surface

Input

wavequides

## **Proximity Perception (short range distance)**

Measure the presence of objects within a specified distance range

- Used to grasp objects and avoid obstacles
- Several technologies:
  - Ultrasonic (low cost)
  - Inductive (ferromagnetic materials at distance <mm)</li>
  - Hall effect (ferromagnetic materials, small, robust, & cheap)
  - Capacitive (any object, binary output, high accuracy when calibrated for a particular object)
  - Optical (infrared light, binary or real valued)
